

CASE STUDY

Scaling a Voice-Based ERP Platform

ROLE Product Manager	CONTEXT Agri-Retail Startup	IMPACT 500% Verification Velocity, 20% Checkout Recovery
--------------------------------	---------------------------------------	--

1. Executive Summary

I led the product evolution for a dual-platform ecosystem: a voice-based ERP for rural retailers and a Buyer Marketplace. By identifying systemic “dead-ends” in UX, technical inaccuracies in checkout logic, and operational bottlenecks in vendor scaling, I successfully took the platform from a stagnant 10-shop pilot to a 60-shop active marketplace.

2. Operational Scaling: Centralizing Vendor Verification

The Problem: The marketplace was stuck at 10 verified shops because verification relied on physical sales visits. This was slow, expensive, and lacked oversight. Shops remained in an “unverified/unvalidated” limbo, unable to transact.

The Action:

- **The Pivot:** I proposed and launched a Centralized Admin Module to enable Tele-Verification.
- **Process Change:** Shifted the “Verified” state trigger from field-sales visits to a centralized Admin check via call-based validation and real-time KYC audit.
- **Impact:** Verified shops grew 6x (10 → 60), including clearing a 50-shop backlog, after shifting verification from field visits to centralized tele-verification.

3. Onboarding UX: Eliminating the “UPI Dead-End”

The Problem: Vendor onboarding had a “Linear Trap.” At the payment setup stage, if a vendor didn't have their UPI ID ready, the app provided no option to skip or go back. Users were forced to close the app, leading to a massive drop-off at the final onboarding step.

The Action:

- **Non-Linear Flow:** Refactored the architecture to a “Profile First, Pay Later” model.
- **The Fix:** Removed redundant steps and turned the UPI field into an Optional/Skip field, ensuring users could complete their registration and start exploring the ERP features immediately.
- **Impact:** Improved onboarding completion rates by 25% within the first month.

4. Revenue Optimization: Fixing the “Price-Jump” Bug

The Problem: The Buyer App was seeing a 45% drop-off at checkout. Because Address Entry occurred after the initial cart calculation, the system performed a “Price Re-sync” (adding taxes/shipping) that was buggy and returned inconsistent totals.

The Action:

- **Technical Audit:** Identified a backend rounding error in the multi-vendor calculation engine that caused “Price Jumps,” killing user trust.
- **Solution:** Standardized the calculation engine into a single “Source of Truth” API and added a real-time price breakdown toggle for transparency.
- **Impact:** Recovered 20% of abandoned carts, increasing monthly successful orders from 175 to 275.

5. Technical Execution & Methodology

- **Data-Led Decision Making:** Used backend logs and funnel analysis to prove that “Cart Drop-offs” were a technical trust issue, not a discovery issue.
- **MCA Advantage:** Personally audited SQL-to-API layers to identify calculation logic errors, bridging the gap between business requirements and engineering.
- **Execution Excellence:** Reduced engineering rework by 25% by including edge-case requirements (noisy environments, low-connectivity) in the initial PRDs.

6. Mockups: UI Improvement for Buyer App [Order Flow]

Fig 1 — Buyer app interface showing flour product listings with category filters, pricing, and add-to-cart options.

Fig 2 — Buyer app UX for scheduling delivery — users can choose immediate or later delivery with time slot selection.

Fig 3 — Interactive calendar and time slot picker for flexible grocery delivery scheduling in the buyer app.

Fig 4 — Buyer app interface showing selected items with scheduled delivery time and store rating.

Fig 5 — Buyer app cart flow showing itemized billing, delivery options, and checkout CTA with promotional messaging.
